# SQL GROUP BY Clause

## Lesson Goals

- Understand how to use the GROUP BY clause
- Understand how to use aggregate functions with the GROUP BY clause to return summary statistics about a column
  - COUNT(), MIN(), MAX(), AVG(), SUM(), STDDEV(), VARIANCE()

## What Are the Elements of the SQL Select Statement?

Faith Kane  
2021

THE BIG 6  
ELEMENTS OF  
A SQL SELECT  
STATEMENT

Necessary

Optional

- 1 SELECT COLUMN\_NAME
- 2 FROM TABLE\_NAME
- 3 WHERE LOGICAL\_CONDITION
- 4 GROUP BY COLUMN\_NAME
- 5 HAVING LOGICAL\_CONDITION
- 6 ORDER BY COLUMN\_NAME

## So What Does Each Element Do?

- Using a GROUP BY clause removes the duplicates from a column just like when we use the DISTINCT SELECT statement.
- Think of using GROUP BY as creating segments of your data and performing analysis on those segments instead of just extracting records.
- GROUP BY allows us to change the level of granularity of our data.
  - For example, changing each row in your return set from representing a single passenger on the Titanic to representing all females or males or all third-class, second-class, and first-class passengers.
- Think of the column(s) that I group by as the dimension(s) of my data and the aggregate function(s) as the measures(s) for my dimension(s).
  - Dimension: A description of what is being measured - discrete value. (can be sorted)
  - Measure: A calculation - continuous value. (can't be sorted)

# THE BIG 6 ELEMENTS OF A SQL SELECT STATEMENT

Necessary

Optional

- 1 **SELECT** IDENTIFIES COLUMN(S)
- 2 **FROM** IDENTIFIES TABLE
- 3 **WHERE** RECORD-FILTERING CRITERIA
- 4 **GROUP BY** SPECIFIES HOW TO GROUP DATA
- 5 **HAVING** GROUP-FILTERING CRITERIA
- 6 **ORDER BY** SPECIFIES ORDER OF RESULTS

## Now What?

- Let's code!

## Using the GROUP BY Clause

- I can return the unique values from a single column or the unique combinations of values from multiple columns.
- Non-aggregated columns in your **SELECT** statement should also be in your **GROUP BY** clause unless they have a 1-to-1 relationship with each other or are at the same level of granularity.

```
USE titanic_db;
```

```
-- Returns 891 records.
```

```
SELECT *  
FROM passengers;
```

```
-- Check out my data types.
```

```
DESCRIBE passengers;
```

```
-- What does a single row or record represent in the passengers table?
```

```
SELECT *  
FROM passengers  
LIMIT 10;
```

- ▼ Now What?
  - Using the GROUP BY Clause
  - Using GROUP BY to Aggregate Data

I can change the granularity or level of detail present in my result set by returning the unique values in a column or grouping by a specific dimension in my table. I can zoom in and out using GROUP BY.

```
-- Since passenger_id is my primary key, each record represents a passenger. How many passengers are in my table? I can do an overall count of the records or rows. (There are 891 passengers in my table.)
```

```
SELECT
    COUNT(*) AS number_of_passengers
FROM passengers;
```

```
-- Return only the unique values from the class column. Now what does a single row represent? Our result set contains much less detail. Zoom out.
```

```
-- Returns 3 rows.
```

```
SELECT
    DISTINCT class
FROM passengers;
```

```
-- The GROUP BY clause returns unique values in ascending order by default.
```

```
SELECT
    class
FROM passengers
GROUP BY class;
```

```
-- If I want to reverse the order of the values, I can use the `DESC` keyword just like with ORDER BY.
```

```
SELECT
    class
FROM passengers
GROUP BY class DESC;
```

```
-- Return only the unique values from the sex column.
```

```
SELECT
    DISTINCT sex
FROM passengers;
```

```
-- The GROUP BY clause returns unique values in ascending order by default.
```

```
SELECT
    sex
FROM passengers
GROUP BY sex;
```

```
-- I can select multiple columns to return all of the unique combinations of values in the selected rows.
```

```
SELECT
    sex,
    class
FROM passengers
GROUP BY sex, class;
```

  - Using the GROUP BY Clause
  - Using GROUP BY to Aggregate Data

## Using GROUP BY to Aggregate Data

- A GROUP BY clause can be combined with an aggregate function to turn a range of numbers into a single data point or summary metric based on a variety of mathematical operations.
  - average, minimum, maximum, count, variance, standard deviation
- If our column contains NULL values, the aggregate function ignores the NULL values.

*-- What if I want to look at the number of rows in a column for each unique value? I can use an aggregate function.*

```
SELECT
    sex,
    COUNT(*) AS number_of_passengers
FROM passengers
GROUP BY sex;
```

*-- The \* returns the count of non-NULL values in the column; I can use the specific column name if I'm not concerned about NULL values.*

```
SELECT
    sex,
    COUNT(sex) AS number_of_passengers
FROM passengers
GROUP BY sex;
```

*-- Check out the difference. Just be aware of this difference when you decide what you pass to the COUNT function.*

```
SELECT
    deck,
    COUNT(deck) AS 'non-null-values',
    COUNT(*) AS 'all_rows'
FROM passengers
GROUP BY deck;
```

*-- What if we want to look at the number of rows for each unique combination of values in multiple columns?*

```
SELECT
    sex,
    class,
    COUNT(*) AS number_of_passengers
FROM passengers
GROUP BY sex, class;
```

*-- Let's choose another dimension and a couple of different measures to further analyze our data. I'm formatting using the ROUND() function.*

```
SELECT
    sex,
    ROUND(AVG(fare), 2) AS average_fare_paid,
    MIN(fare) AS minimum_fare_paid,
    ROUND(MAX(fare), 2) AS maximum_fare_paid,
    ROUND(STDDEV(fare), 2) AS standard_deviation_in_fare
FROM passengers
GROUP BY sex;
```

*-- Let's drill down one more layer by adding the sub-dimension class. I'm basically creating a table of summary statistics for my table.*

```
SELECT
    sex,
    class,
    ROUND(AVG(fare), 2) AS average_fare_paid,
    ROUND(MIN(fare), 2) AS minimum_fare_paid,
    ROUND(MAX(fare), 2) AS maximum_fare_paid,
    ROUND(STDDEV(fare), 2) AS standard_deviation_in_fare
FROM passengers
GROUP BY sex, class;
```
